

## 11.3. Integration, scaling, space-group assignment and post refinement

BY W. KABSCH

### 11.3.1. Introduction

Key steps in the processing of diffraction data from single crystals involve: (a) accurate modelling of the positions of all the reflections recorded in the images; (b) integration of diffraction intensities; (c) data correction, scaling and post refinement; and (d) space-group assignment. Much of the theory and many of the methods for carrying out these steps were developed about two decades ago for processing rotation data recorded on film and were later extended to exploit fully the capabilities of a variety of electronic area detectors; some CCD (charge-coupled device) and multiwire detectors allow the recording of finely sliced rotation data because of their fast data read-out. In this chapter, the principles of the methods are described as they are employed by the program *XDS* (Section 25.2.9). These apply equally well to rotation images covering small or large oscillation ranges. A large number of other systems have been developed which differ in the details of the implementations. Some of these packages are described in Chapter 25.2. The theory and practice of processing fine-sliced data have recently been discussed by Pflugrath (1997).

### 11.3.2. Modelling rotation images

The observed diffraction pattern, *i.e.*, the positions of the reflections recorded in the rotation-data images, is controlled by a small set of parameters which must be accurately determined before integration can start. Approximate values for some of these parameters are given by the experimental setup, whereas others may be completely unknown and must be obtained from the rotation images. This is achieved by automatic location of strong diffraction spots, extraction of a primitive lattice basis that yields integer indices for the observed reflections, and subsequent refinement of all parameters to minimize the discrepancies between observed and calculated spot positions in the data images.

#### 11.3.2.1. Coordinate systems and parameters

In the rotation method, the incident beam wave vector  $\mathbf{S}_0$  of length  $1/\lambda$  ( $\lambda$  is the wavelength) is fixed while the crystal is rotated around a fixed axis described by a unit vector  $\mathbf{m}_2$ .  $\mathbf{S}_0$  points from the X-ray source towards the crystal. It is assumed that the incident beam and the rotation axis intersect at one point at which the crystal must be located. This point is defined as the origin of a right-handed orthonormal laboratory coordinate system  $\{\mathbf{i}_1, \mathbf{i}_2, \mathbf{i}_3\}$ . This fixed but otherwise arbitrary system is used as a reference frame to specify the setup of the diffraction experiment.

Diffraction data are assumed to be recorded on a fixed planar detector. A right-handed orthonormal detector coordinate system  $\{\mathbf{d}_1, \mathbf{d}_2, \mathbf{d}_3\}$  is defined such that a point with coordinates  $X, Y$  in the detector plane is represented by the vector  $(X - X_0)\mathbf{d}_1 + (Y - Y_0)\mathbf{d}_2 + F\mathbf{d}_3$  with respect to the laboratory coordinate system. The origin  $X_0, Y_0$  of the detector plane is found at a distance  $|F|$  from the crystal position. It is assumed that the diffraction data are recorded on adjacent non-overlapping rotation images, each covering a constant oscillation range  $\Delta_\varphi$  with image No. 1 starting at spindle angle  $\varphi_0$ .

Diffraction geometry is conveniently expressed with respect to a right-handed orthonormal goniostat system  $\{\mathbf{m}_1, \mathbf{m}_2, \mathbf{m}_3\}$ . It is constructed from the rotation axis and the incident beam direction such that  $\mathbf{m}_1 = (\mathbf{m}_2 \times \mathbf{S}_0)/|\mathbf{m}_2 \times \mathbf{S}_0|$  and  $\mathbf{m}_3 = \mathbf{m}_1 \times \mathbf{m}_2$ . The origin of the goniostat system is defined to coincide with the origin of the laboratory system.

Finally, a right-handed crystal coordinate system  $\{\mathbf{b}_1, \mathbf{b}_2, \mathbf{b}_3\}$  and its reciprocal basis  $\{\mathbf{b}_1^*, \mathbf{b}_2^*, \mathbf{b}_3^*\}$  are defined to represent the unrotated crystal, *i.e.*, at rotation angle  $\varphi = 0^\circ$ , such that any reciprocal-lattice vector can be expressed as  $\mathbf{p}_0^* = h\mathbf{b}_1^* + k\mathbf{b}_2^* + l\mathbf{b}_3^*$  where  $h, k, l$  are integers.

Using a Gaussian model, the shape of the diffraction spots is specified by two parameters: the standard deviations of the reflecting range  $\sigma_M$  and the beam divergence  $\sigma_D$  (see Section 11.3.2.3). This leads to an integration region around the spot defined by the parameters  $\delta_M$  and  $\delta_D$ , which are typically chosen to be 6–10 times larger than  $\sigma_M$  and  $\sigma_D$ , respectively.

Knowledge of the parameters  $\mathbf{S}_0, \mathbf{m}_2, \mathbf{b}_1, \mathbf{b}_2, \mathbf{b}_3, X_0, Y_0, F, \mathbf{d}_1, \mathbf{d}_2, \mathbf{d}_3, \varphi_0$  and  $\Delta_\varphi$  is sufficient to compute the location of all diffraction peaks recorded in the data images. Determination and refinement of these parameters are described in the following sections.

#### 11.3.2.2. Spot prediction

It is assumed here that accurate values of all parameters describing the diffraction experiment are available, permitting prediction of the positions of all diffraction peaks recorded in the data images. Let  $\mathbf{p}_0^*$  denote any arbitrary reciprocal-lattice vector if the crystal has not been rotated, *i.e.*, at rotation angle  $\varphi = 0^\circ$ .  $\mathbf{p}_0^*$  can be expressed by its components with respect to the orthonormal goniostat system as

$$\mathbf{p}_0^* = \mathbf{m}_1(\mathbf{m}_1 \cdot \mathbf{p}_0^*) + \mathbf{m}_2(\mathbf{m}_2 \cdot \mathbf{p}_0^*) + \mathbf{m}_3(\mathbf{m}_3 \cdot \mathbf{p}_0^*).$$

Depending on the diffraction geometry,  $\mathbf{p}_0^*$  may be rotated into a position fulfilling the reflecting condition. The required rotation angle  $\varphi$  and the coordinates  $X, Y$  of the diffracted beam at its intersection with the detector plane can be found from  $\mathbf{p}_0^*$  as follows.

Rotation by  $\varphi$  around axis  $\mathbf{m}_2$  changes  $\mathbf{p}_0^*$  into  $\mathbf{p}^*$ .

$$\begin{aligned} \mathbf{p}^* &= D(\mathbf{m}_2, \varphi)\mathbf{p}_0^* = \mathbf{m}_2(\mathbf{m}_2 \cdot \mathbf{p}_0^*) + [\mathbf{p}_0^* - \mathbf{m}_2(\mathbf{m}_2 \cdot \mathbf{p}_0^*)] \cos \varphi \\ &\quad + \mathbf{m}_2 \times \mathbf{p}_0^* \sin \varphi \\ &= \mathbf{m}_1(\mathbf{m}_1 \cdot \mathbf{p}_0^* \cos \varphi + \mathbf{m}_3 \cdot \mathbf{p}_0^* \sin \varphi) + \mathbf{m}_2 \mathbf{m}_2 \cdot \mathbf{p}_0^* \\ &\quad + \mathbf{m}_3(\mathbf{m}_3 \cdot \mathbf{p}_0^* \cos \varphi - \mathbf{m}_1 \cdot \mathbf{p}_0^* \sin \varphi) \\ &= \mathbf{m}_1(\mathbf{m}_1 \cdot \mathbf{p}^*) + \mathbf{m}_2(\mathbf{m}_2 \cdot \mathbf{p}^*) + \mathbf{m}_3(\mathbf{m}_3 \cdot \mathbf{p}^*). \end{aligned}$$

The incident and diffracted beam wave vectors,  $\mathbf{S}_0$  and  $\mathbf{S}$ , have their termini on the Ewald sphere and satisfy the Laue equations

$$\mathbf{S} = \mathbf{S}_0 + \mathbf{p}^*, \quad \mathbf{S}^2 = \mathbf{S}_0^2 \implies \mathbf{p}^{*2} = -2\mathbf{S}_0 \cdot \mathbf{p}^* = \mathbf{p}_0^{*2}.$$

If  $\rho = [\mathbf{p}_0^{*2} - (\mathbf{p}_0^* \cdot \mathbf{m}_2)^2]^{1/2}$  denotes the distance of  $\mathbf{p}_0^*$  from the rotation axis, solutions for  $\mathbf{p}^*$  and  $\varphi$  can be obtained in terms of  $\mathbf{p}_0^*$  as

$$\begin{aligned} \mathbf{p}^* \cdot \mathbf{m}_3 &= [-\mathbf{p}_0^{*2}/2 - (\mathbf{p}_0^* \cdot \mathbf{m}_2)(\mathbf{S}_0 \cdot \mathbf{m}_2)]/\mathbf{S}_0 \cdot \mathbf{m}_3 \\ \mathbf{p}^* \cdot \mathbf{m}_2 &= \mathbf{p}_0^* \cdot \mathbf{m}_2 \\ \mathbf{p}^* \cdot \mathbf{m}_1 &= \pm[\rho^2 - (\mathbf{p}^* \cdot \mathbf{m}_3)^2]^{1/2} \\ \cos \varphi &= [(\mathbf{p}^* \cdot \mathbf{m}_1)(\mathbf{p}_0^* \cdot \mathbf{m}_1) + (\mathbf{p}^* \cdot \mathbf{m}_3)(\mathbf{p}_0^* \cdot \mathbf{m}_3)]/\rho^2 \\ \sin \varphi &= [(\mathbf{p}^* \cdot \mathbf{m}_1)(\mathbf{p}_0^* \cdot \mathbf{m}_3) - (\mathbf{p}^* \cdot \mathbf{m}_3)(\mathbf{p}_0^* \cdot \mathbf{m}_1)]/\rho^2. \end{aligned}$$

In general, there are two solutions according to the sign of  $\mathbf{p}^* \cdot \mathbf{m}_1$ . If  $\rho^2 < (\mathbf{p}^* \cdot \mathbf{m}_3)^2$  or  $\mathbf{p}_0^{*2} > 4\mathbf{S}_0^2$ , the Laue equations have no solution and the reciprocal-lattice point  $\mathbf{p}_0^*$  is in the 'blind' region.

If  $F\mathbf{S} \cdot \mathbf{d}_3 > 0$ , the diffracted beam intersects the detector plane at the point
